

## nag\_1d\_quad\_inf (d01amc)

### 1. Purpose

**nag\_1d\_quad\_inf (d01amc)** calculates an approximation to the integral of a function  $f(x)$  over an infinite or semi-infinite interval  $[a, b]$ :

$$I = \int_a^b f(x) dx.$$

### 2. Specification

```
#include <nag.h>
#include <nagd01.h>
```

```
void nag_1d_quad_inf(double (*f)(double x), Nag_BoundInterval boundinf,
                    double bound, double epsabs, double epsrel, Integer
                    max_num_subint, double *result, double *abserr,
                    Nag_QuadProgress *qp, NagError *fail)
```

### 3. Description

**nag\_1d\_quad\_inf** is based on the QUADPACK routine QAGI (Piessens *et al* (1983)). The entire infinite integration range is first transformed to  $[0, 1]$  using one of the identities:

$$\int_{-\infty}^a f(x) dx = \int_0^1 f\left(a - \frac{1-t}{t}\right) \frac{1}{t^2} dt$$

$$\int_a^{\infty} f(x) dx = \int_0^1 f\left(a + \frac{1-t}{t}\right) \frac{1}{t^2} dt$$

$$\int_{-\infty}^{\infty} f(x) dx = \int_0^{\infty} (f(x) + f(-x)) dx = \int_0^1 \left[ f\left(\frac{1-t}{t}\right) + f\left(\frac{-1+t}{t}\right) \right] \frac{1}{t^2} dt$$

where  $a$  represents a finite integration limit. An adaptive procedure, based on the Gauss 7-point and Kronrod 15-point rules, is then employed on the transformed integral. The algorithm, described by de Doncker (1978), incorporates a global acceptance criterion (as defined by Malcolm and Simpson (1976)) together with the  $\epsilon$ -algorithm (Wynn (1956)) to perform extrapolation. The local error estimation is described by Piessens *et al* (1983).

### 4. Parameters

**f**

The function **f**, supplied by the user, must return the value of the integrand  $f$  at a given point.

The specification of **f** is:

```
double f(double x)

    x
    Input: the point at which the integrand  $f$  must be evaluated.
```

**boundinf**

Input: indicates the kind of integration interval:

if **boundinf** = **Nag\_UpperSemiInfinite**, the interval is  $[\text{bound}, +\infty)$

if **boundinf** = **Nag\_LowerSemiInfinite**, the interval is  $(-\infty, \text{bound}]$

if **boundinf** = **Nag\_Infinite**, the interval is  $(-\infty, +\infty)$

Constraint: **boundinf** = **Nag\_UpperSemiInfinite**, **Nag\_LowerSemiInfinite**, or **Nag\_Infinite**.

**bound**

Input: the finite limit of the integration interval (if present). **bound** is not used if **boundinf** = Nag\_Infinite.

**epsabs**

Input: the absolute accuracy required. If **epsabs** is negative, the absolute value is used. See Section 6.1.

**epsrel**

Input: the relative accuracy required. If **epsrel** is negative, the absolute value is used. See Section 6.1.

**max\_num\_subint**

Input: the upper bound on the number of sub-intervals into which the interval of integration may be divided by the function. The more difficult the integrand, the larger **max\_num\_subint** should be.

Suggested value: a value in the range 200 to 500 is adequate for most problems.

Constraint: **max\_num\_subint**  $\geq 1$ .

**result**

Output: the approximation to the integral  $I$ .

**abserr**

Output: an estimate of the modulus of the absolute error, which should be an upper bound for  $|I - \text{result}|$ .

**qp**

Pointer to structure of type Nag\_QuadProgress with the following members:

**num\_subint** – Integer

Output: the actual number of sub-intervals used.

**fun\_count** – Integer

Output: the number of function evaluations performed by nag\_1d\_quad\_inf.

**sub\_int\_beg\_pts** – double \*

**sub\_int\_end\_pts** – double \*

**sub\_int\_result** – double \*

**sub\_int\_error** – double \*

Output: these pointers are allocated memory internally with **max\_num\_subint** elements. If an error exit other than **NE\_INT\_ARG\_LT**, **NE\_BAD\_PARAM** or **NE\_ALLOC\_FAIL**, occurs, these arrays will contain information which may be useful. For details, see Section 6. If nag\_1d\_quad\_inf is to be called repeatedly, then the user should free the storage allocated by these pointers before any subsequent call is made.

**fail**

The NAG error parameter, see the Essential Introduction to the NAG C Library.

Users are recommended to declare and initialize **fail** and set **fail.print** = TRUE for this function.

## 5. Error Indications and Warnings

**NE\_INT\_ARG\_LT**

On entry, **max\_num\_subint** must not be less than 1: **max\_num\_subint** =  $\langle \text{value} \rangle$ .

**NE\_BAD\_PARAM**

On entry, parameter **boundinf** had an illegal value.

**NE\_ALLOC\_FAIL**

Memory allocation failed.

**NE\_QUAD\_MAX\_SUBDIV**

The maximum number of subdivisions has been reached: **max\_num\_subint** =  $\langle \text{value} \rangle$ .

The maximum number of subdivisions has been reached without the accuracy requirements being achieved. Look at the integrand in order to determine the integration difficulties. If the

position of a local difficulty within the interval can be determined (e.g. a singularity of the integrand or its derivative, a peak, a discontinuity, etc.) you will probably gain from splitting up the interval at this point and calling the integrator on the sub-intervals. If necessary, another integrator, which is designed for handling the type of difficulty involved, must be used. Alternatively, consider relaxing the accuracy requirements specified by **epsabs** and **epsrel**, or increasing the value of **max\_num\_subint**.

#### **NE\_QUAD\_ROUNDOFF\_TOL**

Round-off error prevents the requested tolerance from being achieved: **epsabs** =  $\langle \text{value} \rangle$ , **epsrel** =  $\langle \text{value} \rangle$ .

The error may be underestimated. Consider relaxing the accuracy requirements specified by **epsabs** and **epsrel**.

#### **NE\_QUAD\_BAD\_SUBDIV**

Extremely bad integrand behaviour occurs around the sub-interval ( $\langle \text{value} \rangle$ ,  $\langle \text{value} \rangle$ ).

The same advice applies as in the case of **NE\_QUAD\_MAX\_SUBDIV**.

#### **NE\_QUAD\_ROUNDOFF\_EXTRAPL**

Round-off error is detected during extrapolation.

The requested tolerance cannot be achieved, because the extrapolation does not increase the accuracy satisfactorily; the returned result is the best that can be obtained.

The same advice applies as in the case of **NE\_QUAD\_MAX\_SUBDIV**.

#### **NE\_QUAD\_NO\_CONV**

The integral is probably divergent or slowly convergent.

Please note that divergence can also occur with any error exit other than **NE\_INT\_ARG\_LT**, **NE\_BAD\_PARAM** or **NE\_ALLOC\_FAIL**.

#### **NE\_QUAD\_BAD\_SUBDIV\_INTS**

Extremely bad integrand behaviour occurs around one of the sub-intervals ( $\langle \text{value} \rangle$ ,  $\langle \text{value} \rangle$ ) or ( $\langle \text{value} \rangle$ ,  $\langle \text{value} \rangle$ ).

The same advice applies as in the case of **NE\_QUAD\_MAX\_SUBDIV**.

## 6. Further Comments

The time taken by the function depends on the integrand and the accuracy required.

If the function fails with an error exit other than **NE\_INT\_ARG\_LT**, **NE\_BAD\_PARAM** or **NE\_ALLOC\_FAIL** then the user may wish to examine the contents of the structure **qp**. These contain the end-points of the sub-intervals used by **nag\_1d\_quad\_inf** along with the integral contributions and error estimates over the sub-intervals.

Specifically, for  $i = 1, 2, \dots, n$ , let  $r_i$  denote the approximation to the value of the integral over the sub-interval  $[a_i, b_i]$  in the partition of  $[a, b]$  and  $e_i$  be the corresponding absolute error estimate.

Then,  $\int_{a_i}^{b_i} f(x) dx \simeq r_i$  and **result** =  $\sum_{i=1}^n r_i$  unless **nag\_1d\_quad\_inf** terminates while testing for divergence of the integral (see Piessens *et al* (1983), Section 3.4.3). In this case, **result** (and **abserr**) are taken to be the values returned from the extrapolation process. The value of  $n$  is returned in **num\_subint**, and the values  $a_i$ ,  $b_i$ ,  $r_i$  and  $e_i$  are stored in the structure **qp** as

$$\begin{aligned} a_i &= \text{sub\_int\_beg\_pts}[i - 1], \\ b_i &= \text{sub\_int\_end\_pts}[i - 1], \\ r_i &= \text{sub\_int\_result}[i - 1] \quad \text{and} \\ e_i &= \text{sub\_int\_error}[i - 1]. \end{aligned}$$

### 6.1. Accuracy

The function cannot guarantee, but in practice usually achieves, the following accuracy:

$$|I - \text{result}| \leq \text{tol}$$

where

$$\text{tol} = \max\{|\text{epsabs}|, |\text{epsrel}| \times |I|\}$$

and **epsabs** and **epsrel** are user-specified absolute and relative error tolerances. Moreover it returns the quantity **abserr** which, in normal circumstances, satisfies

$$|I - \text{result}| \leq \text{abserr} \leq \text{tol}.$$
