nag_1d_quad_wt_cauchy_1 (d01sqc)

1. Purpose

nag_1d_quad_wt_cauchy_1 (d01sqc) calculates an approximation to the Hilbert transform of a function $g(x)$ over $[a, b]$:

$$I = \int_a^b \frac{g(x)}{x - c} \, dx$$

for user-specified values of a, b and c.

2. Specification

```
#include <nag.h>
#include <nagd01.h>

void nag_1d_quad_wt_cauchy_1(double (*g)(double x, Nag_User *comm),
          double a, double b, double c, double epsabs, double epsrel,
          Integer max_num_subint, double *result, double *abserr,
          Nag_QuadProgress *qp, Nag_User *comm, NagError *fail)
```

3. Description

This function is based upon the QUADPACK routine QAWC (Piessens *et al.* (1983)) and integrates a function of the form $g(x)w(x)$, where the weight function

$$w(x) = \frac{1}{x - c}$$

is that of the Hilbert transform. (If $a < c < b$ the integral has to be interpreted in the sense of a Cauchy principal value.) It is an adaptive routine which employs a 'global' acceptance criterion (as defined by Malcolm and Simpson (1976)). Special care is taken to ensure that c is never the end-point of a sub-interval (Piessens *et al.* (1976)). On each sub-interval (c_1, c_2) modified Clenshaw–Curtis integration of orders 12 and 24 is performed if $c_1 - d \leq c \leq c_2 + d$ where $d = (c_2 - c_1)/20$. Otherwise the Gauss 7-point and Kronrod 15-point rules are used. The local error estimation is described by Piessens *et al.* (1983).

4. Parameters

g

The function **g**, supplied by the user, must return the value of the function g at a given point. The specification of **g** is:

```
double g(double x, Nag_User *comm)
```

> **x**
>
> Input: the point at which the function g must be evaluated.
>
> **comm**
>
> Input/Output: pointer to a structure of type Nag_User with the following member:
>
> **p** - Pointer
>
> Input/Output: the pointer **comm->p** should be cast to the required type, e.g. `struct user *s = (struct user *)comm->p`, to obtain the original object's address with appropriate type. (See the argument **comm** below.)

a

Input: the lower limit of integration, a.

b

Input: the upper limit of integration, b. It is not necessary that $a < b$.

c
> Input: the parameter c in the weight function.
> Constraints: $\mathbf{c} \neq \mathbf{a}$ or $\mathbf{c} \neq \mathbf{b}$

epsabs
> Input: the absolute accuracy required. If **epsabs** is negative, the absolute value is used. See Section 6.1.

epsrel
> Input: the relative accuracy required. If **epsrel** is negative, the absolute value is used. See Section 6.1.

max_num_subint
> Input: the upper bound on the number of sub-intervals into which the interval of integration may be divided by the function. The more difficult the integrand, the larger **max_num_subint** should be.
> Suggested value: a value in the range 200 to 500 is adequate for most problems.
> Constraint: **max_num_subint** ≥ 1.

result
> Output: the approximation to the integral I.

abserr
> Output: an estimate of the modulus of the absolute error, which should be an upper bound for $|I-\mathbf{result}|$.

qp
> Pointer to structure of type Nag_QuadProgress with the following members:
>
> **num_subint** – Integer
> > Output: the actual number of sub-intervals used.
>
> **fun_count** – Integer
> > Output: the number of function evaluations performed by this function.
>
> **sub_int_beg_pts** – double *
> **sub_int_end_pts** – double *
> **sub_int_result** – double *
> **sub_int_error** – double *
> > Output: these pointers are allocated memory internally with **max_num_subint** elements. If an error exit other than **NE_INT_ARG_LT**, **NE_2_REAL_ARG_EQ** or **NE_ALLOC_FAIL** occurs, these arrays will contain information which may be useful. For details, see Section 6. If this function is to be called repeatedly, then the user should free the storage allocated by these pointers before any subsequent call is made.

comm
> Input/Output: pointer to a structure of type Nag_User with the following member:
>
> **p** - Pointer
> > Input/Output: the pointer **p**, of type Pointer, allows the user to communicate information to and from the user-defined function **g()**. An object of the required type should be declared by the user, e.g. a structure, and its address assigned to the pointer **p** by means of a cast to Pointer in the calling program, e.g. `comm.p = (Pointer)&s`. The type pointer will be `void *` with a C compiler that defines `void *` and `char *` otherwise.

fail
> The NAG error parameter, see the Essential Introduction to the NAG C Library.
> Users are recommended to declare and initialize **fail** and set **fail.print** = TRUE for this function.

5.   Error Indications and Warnings

NE_INT_ARG_LT
> On entry, **max_num_subint** must not be less than 1: **max_num_subint** = ⟨*value*⟩.

NE_2_REAL_ARG_EQ

On entry, $\mathbf{c} = \langle value \rangle$ while $\mathbf{a} = \langle value \rangle$. These parameters must satisfy $\mathbf{c} \neq \mathbf{a}$.
On entry, $\mathbf{c} = \langle value \rangle$ while $\mathbf{b} = \langle value \rangle$. These parameters must satisfy $\mathbf{c} \neq \mathbf{b}$.

NE_ALLOC_FAIL

Memory allocation failed.

NE_QUAD_MAX_SUBDIV

The maximum number of subdivisions has been reached: **max_num_subint** $= \langle value \rangle$.
The maximum number of subdivisions has been reached without the accuracy requirements being achieved. Look at the integrand in order to determine the integration difficulties. Another integrator, which is designed for handling the type of difficulty involved, must be used. Alternatively, consider relaxing the accuracy requirements specified by **epsabs** and **epsrel**, or increasing the value of **max_num_subint**.

NE_QUAD_ROUNDOFF_TOL

Round-off error prevents the requested tolerance from being achieved: **epsabs** $= \langle value \rangle$, **epsrel** $= \langle value \rangle$.
The error may be underestimated. Consider relaxing the accuracy requirements specified by **epsabs** and **epsrel**.

NE_QUAD_BAD_SUBDIV

Extremely bad integrand behaviour occurs around the sub-interval $(\langle value \rangle, \langle value \rangle)$.
The same advice applies as in the case of **NE_QUAD_MAX_SUBDIV**.

6. Further Comments

The time taken by the function depends on the integrand and the accuracy required.

If the function fails with an error exit other than **NE_INT_ARG_LT**, **NE_2_REAL_ARG_EQ** or **NE_ALLOC_FAIL**, then the user may wish to examine the contents of the structure **qp**. These contain the end-points of the sub-intervals used by this function along with the integral contributions and error estimates over the sub-intervals.

Specifically, for $i = 1, 2, \ldots, n$, let r_i denote the approximation to the value of the integral over the sub-interval $[a_i, b_i]$ in the partition of $[a, b]$ and e_i be the corresponding absolute error estimate.

Then, $\int_{a_i}^{b_i} g(x)w(x) \, dx \simeq r_i$ and **result** $= \sum_{i=1}^{n} r_i$.

The value of n is returned in **num_subint**, and the values a_i, b_i, r_i and e_i are stored in the structure **qp** as

$$a_i = \textbf{sub\_int\_beg\_pts}[i - 1],$$
$$b_i = \textbf{sub\_int\_end\_pts}[i - 1],$$
$$r_i = \textbf{sub\_int\_result}[i - 1] \text{ and}$$
$$e_i = \textbf{sub\_int\_error}[i - 1].$$

6.1. Accuracy

The function cannot guarantee, but in practice usually achieves, the following accuracy:

$$|I - \textbf{result}| \leq tol$$

where

$$tol = \max\{|\textbf{epsabs}|, |\textbf{epsrel}| \times |I|\}$$

and **epsabs** and **epsrel** are user-specified absolute and relative error tolerances. Moreover it returns the quantity **abserr** which, in normal circumstances, satisfies

$$|I - \textbf{result}| \leq \textbf{abserr} \leq tol.$$
