

# F02FQFP

## NAG Parallel Library Routine Document

**Note:** Before using this routine, please read the Users' Note for your implementation to check for implementation-dependent details. You are advised to enclose any calls to NAG Parallel Library routines between calls to Z01AAFP and Z01ABFP.

### 1 Description

F02FQFP computes the eigenvalues and eigenvectors (the spectral decomposition) of a real symmetric matrix whose columns are distributed on a logical 2-d processor grid.

The spectral decomposition of an  $n \times n$  real symmetric matrix  $A$  may be defined in the form

$$A = Z\Lambda Z^T$$

where  $Z$  is an  $n \times n$  orthogonal matrix of eigenvectors and  $\Lambda$  is an  $n \times n$  diagonal matrix of eigenvalues.

### 2 Specification

```
SUBROUTINE F02FQFP(ICNTXT, N, A, LDA, NX, IFAIL)
DOUBLE PRECISION  A(0:LDA-1,0:*)
INTEGER           ICNTXT, N, LDA, NX, IFAIL
```

### 3 Data Distribution

#### 3.1 Definitions

The following definitions are used in describing the data distribution within this document:

- $m_p$  – the number of rows in the logical processor grid.
- $n_p$  – the number of columns in the logical processor grid.
- $p$  –  $m_p \times n_p$ , the total number of processors in the logical processor grid.
- $p_d$  – the number of logical processors which hold columns of the matrix  $A$ .
- $N_b$  – the maximum number of columns of the matrix  $A$  held locally on a logical processor.
- $N_x$  – the actual number of columns of the matrix  $A$  held locally on a logical processor, where  $0 \leq N_x \leq N_b$ .
- $[x]$  – the ceiling function of  $x$  which gives the smallest integer which is not less than  $x$ .

#### 3.2 Global and Local Arguments

The input arguments  $N$  and  $IFAIL$  are global and so must have the same value on entry to the routine on each processor. The output argument  $IFAIL$  is also global and so will have the same value on exit from the routine on each processor. The remaining arguments are local.

#### 3.3 Distribution Strategy

Columns of the matrix  $A$  are allocated to logical processors on the 2-d grid row by row (i.e., in row major ordering of the grid) starting from the  $\{0,0\}$  logical processor. Each logical processor that contains columns of the matrix contains  $N_b = \lceil n/p \rceil$  columns, except the last processor that actually contains data, for which the number of columns held may be less than  $N_b$ . This processor will contain  $\text{mod}(n, N_b)$  columns if  $\text{mod}(n, N_b) \neq 0$ , and will contain  $N_b$  columns otherwise. Some logical processors may not contain any columns of the matrix if  $n$  is not large relative to  $p$ , but if  $n > (p-1)^2$  then all processors will certainly contain columns of the matrix.

The number of logical processors that contain columns of the matrix is given by  $p_d = \lceil n/N_b \rceil$ .

The following example illustrates a case where the last processor with data is not the last processor of the grid. Furthermore the number of columns on the last processor with data is not equal to the number of columns on other processors.

If  $m_p = 2$ ,  $n_p = 4$  then  $p = m_p \times n_p = 8$ . If  $n = 41$  then  $N_b = \lceil n/p \rceil = \lceil 5.125 \rceil = 6$ ,  $\text{mod}(n, N_b) = 5 \neq 0$  and  $p_d = \lceil n/N_b \rceil = \lceil 6.833 \rceil = 7$ .

processor {0,0} $N_x = 6$ columns (1:6)	processor {0,1} $N_x = 6$ columns (7:12)	processor {0,2} $N_x = 6$ columns (13:18)	processor {0,3} $N_x = 6$ columns (19:24)
processor {1,0} $N_x = 6$ columns (25:30)	processor {1,1} $N_x = 6$ columns (31:36)	processor {1,2} $N_x = 5$ columns (37:41)	processor {1,3} $N_x = 0$

If the data is distributed incorrectly, the routine may fail to produce correct results or will exit with an error flag. Routines to assist with distribution of data can be found in Chapters F01 and X04.

## 4 Arguments

- 1: ICNTXT — INTEGER *Local Input*

*On entry:* the BLACS context used by the communication mechanism, usually returned by a call to Z01AAFP.

- 2: N — INTEGER *Global Input*

*On entry:*  $n$ , the order of the matrix  $A$ .

*Constraint:*  $N \geq 0$ .

- 3: A(0:LDA-1,0:\*) — DOUBLE PRECISION array *Local Input/Local Output*

**Note:** the size of the second dimension of the array  $A$  must be at least  $N_x + 1$  where  $N_x$  is the number of columns of  $A$  held locally by the logical processor. The array  $A$  is not referenced if  $N_x = 0$ .

*On entry:*  $A(1 : n, 1 : N_x)$  must contain columns of the matrix  $A$  as defined by the distribution strategy (see Section 3.3).

*On exit:*  $A(0, 1 : N_x)$  contains  $N_x$  eigenvalues of the matrix  $A$  stored on this logical processor. They are ordered locally and globally (in the row major ordering of the processors) in non-decreasing order of magnitude.

$A(1 : n, 1 : N_x)$  contains the eigenvectors corresponding to the eigenvalues kept on this logical processor.

The remainder of the array is used as workspace and contains no useful information.

- 4: LDA — INTEGER *Local Input*

*On entry:* the size of the first dimension of the array  $A$  as declared in the (sub)program from which F02FQFP is called.

*Constraint:*  $LDA \geq 2 \times N + 2$ .

- 5: NX — INTEGER *Local Output*

*On exit:*  $N_x$ , the number of columns of the matrix  $A$  held on the logical processor. This is also equal to the number of eigenvalues held by the logical processor.

- 6: IFAIL — INTEGER *Global Input/Global Output*

*On entry:* IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended values are:

IFAIL = 0, if multigridding is **not** employed;

IFAIL = -1, if multigridding is employed.

*On exit:* IFAIL = 0 unless the routine detects an error (see Section 5).

## 5 Errors and Warnings

If on entry  $IFAIL = 0$  or  $-1$ , explanatory error messages are output from the root processor (or processor  $\{0,0\}$  when the root processor is not available) on the current error message unit (as defined by  $X04AAF$ ).

Errors detected by the routine:

$IFAIL = -2000$

The routine has been called with an invalid value of  $ICNTXT$  on one or more processors.

$IFAIL = -1000$

The logical processor grid and library mechanism (Library Grid) have not been correctly defined, see  $Z01AAFP$ .

$IFAIL = -i$

On entry, the  $i$ th argument had an invalid value. This error occurred either because a global argument did not have the same value on all logical processors, or because its value on one or more processors was incorrect. An explanatory message distinguishes between these two cases.

$IFAIL = 1$

The Jacobi algorithm has not converged.

## 6 Further Comments

### 6.1 Algorithmic Detail

The algorithm is based on an one-sided Jacobi method, see Hestenes [2].

### 6.2 Parallelism Detail

The algorithm uses a linear array of logical processors. This linear array is mapped to the 2-d array based on the row major ordering beginning from the  $\{0,0\}$  logical processor on the 2-d array. Most of the communication is between neighbours on the linear array of processors.

### 6.3 Accuracy

The computed factors  $\Lambda$  and  $Z$  satisfy the relation

$$Z\Lambda Z^T = A + E,$$

where

$$\|E\| \leq c\epsilon\|A\|,$$

$\epsilon$  being the *machine precision*,  $c$  is a modest function of  $n$  and  $\|\cdot\|$  denotes the 2-norm.

## 8 Example

To find the eigenvalues and eigenvectors of the 7 by 7 matrix  $A$  given by

$$A = \begin{pmatrix} 1.0 & 2.0 & 3.0 & 4.0 & 5.0 & 6.0 & 7.0 \\ 2.0 & 2.0 & 3.0 & 4.0 & 5.0 & 6.0 & 7.0 \\ 3.0 & 3.0 & 3.0 & 4.0 & 5.0 & 6.0 & 7.0 \\ 4.0 & 4.0 & 4.0 & 4.0 & 5.0 & 6.0 & 7.0 \\ 5.0 & 5.0 & 5.0 & 5.0 & 5.0 & 6.0 & 7.0 \\ 6.0 & 6.0 & 6.0 & 6.0 & 6.0 & 6.0 & 7.0 \\ 7.0 & 7.0 & 7.0 & 7.0 & 7.0 & 7.0 & 7.0 \end{pmatrix}$$

and to print the results on the root processor. The routine F01ZRFP is used to generate the matrix  $A$  on a 2 by 2 logical processor grid. The number of columns of the matrix  $A$  on each logical processor,  $N_x$ , is equal to 2 on logical processors  $\{0,0\}$ ,  $\{0,1\}$ , and  $\{1,0\}$ . On the final logical processor  $\{1,1\}$ ,  $N_x = 1$ .

The routine X04BFFP is used to bring eigenvalues to the root processor and print them. The same routine is called again to print the eigenvectors.
